Monogamy-of-entanglement games

Open questions

Nonlocal games

Nonlocal games

A nonlocal game is a cooperative game played between Alice and Bob against a referee.

- 1. Question and answer sets: (Σ_A, Σ_B) and (Γ_A, Γ_B) ,
- 2. Distributions on question pairs: $\pi: \Sigma_A \times \Sigma_B \to [0,1]$,
- 3. A predicate $V: \Gamma_A \times \Gamma_B \times \Sigma_A \times \Sigma_B \rightarrow \{0,1\}$, where

$$V(a,b|x,y) = \begin{cases} 1 & \text{if Alice and Bob win,} \\ 0 & \text{if Alice and Bob lose.} \end{cases}$$

Strategies and values for nonlocal games

Alice and Bob could use different types of strategies:

- ▶ Classical strategies: Alice and Bob answer deterministically, determined by functions of $f: \Sigma_A \to \Gamma_A$ and $g: \Sigma_B \to \Gamma_B$.
- ▶ Quantum strategies: Alice and Bob share a joint quantum system $\rho \in D(\mathcal{A} \otimes \mathcal{B})$ and allow their answers to be outcomes of measurements on this shared system.

Strategies and values for nonlocal games

Alice and Bob could use different types of strategies:

- ▶ Classical strategies: Alice and Bob answer deterministically, determined by functions of $f: \Sigma_A \to \Gamma_A$ and $g: \Sigma_B \to \Gamma_B$.
- ▶ Quantum strategies: Alice and Bob share a joint quantum system $\rho \in D(\mathcal{A} \otimes \mathcal{B})$ and allow their answers to be outcomes of measurements on this shared system.

The *value* of a nonlocal game is the maximal winning probability for the players to win over all strategies of a specified type.

For a nonlocal game, G, we denote the classical and quantum values as

- Classical value: $\omega(G)$,
- Quantum value: $\omega^*(G)$.

Example: The CHSH game

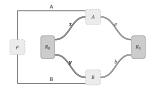

The CHSH game (G_{CHSH}). Question and answer sets over $\{0,1\}$. Question pairs $\{00,01,10,11\}$ selected with equal probability. Winning condition iff $a \oplus b = x \wedge y$.

$$\omega(G_{\mathsf{CHSH}}) < \omega^*(G_{\mathsf{CHSH}})$$

• $\omega(G_{\text{CHSH}}) = \frac{3}{4} = 0.75$:

• $\omega^*(G_{CHSH}) = \cos^2(\frac{\pi}{8}) \approx 0.8536$:

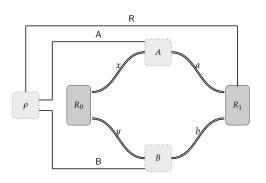

Demo Time: CHSH game in QETLAB CHSH_GAME.M

Extended nonlocal games

Extended nonlocal games

An extended nonlocal game is a nonlocal game where the referee also holds a quantum system that he measures provided by Alice and Bob.

- 1. Question and answer sets (Σ_A, Σ_B) and (Γ_A, Γ_B) .
- 2. Distribution on question pairs: $\pi: \Sigma_A \times \Sigma_B \to [0,1]$.
- 3. A measurement operator $V: \Gamma_A \times \Gamma_B \times \Sigma_A \times \Sigma_B \to Pos(\mathcal{R})$.

Extended nonlocal games: Winning and losing probabilities

At the end of the protocol, the referee has:

1. The state at the end of the protocol:

$$\rho_{a,b}^{x,y} \in D(\mathcal{R}).$$

2. A measurement the referee makes on its part of the state ρ :

$$V(a, b|x, y) \in Pos(\mathcal{R}).$$

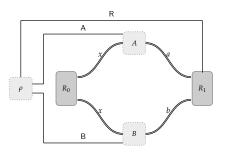

The respective winning and losing probabilities are given by

$$\left\langle V(a,b|x,y),
ho_{a,b}^{x,y} \right
angle \quad \text{and} \quad \left\langle \mathbb{1} - V(a,b|x,y),
ho_{a,b}^{x,y} \right
angle.$$

Monogamy-of-entanglement games

Monogamy-of-entanglement games

Monogamy-of-entanglement games \P , are a special type of extended nonlocal game.

- 1. Same question and answer sets: $\Sigma=\Sigma_A=\Sigma_B$ and $\Gamma=\Gamma_A=\Gamma_B.$
- 2. Alice and Bob get the same question: $\pi(x, y) = 0$ for $x \neq y$.
- 3. Referee's measurement operator: $R: \Sigma \times \Gamma \to \operatorname{Pos}(\mathcal{R})$.
- 4. Winning condition: Iff Alice's output, Bob's output, and the referee's output are all the *equal*.

¶[Tomamichel, Fehr, Kaniewski, Wehner, (2013)]

Standard quantum strategies for monogamy-of-entanglement games

A standard quantum strategy consists of a tripartite state $\rho \in D(\mathcal{R} \otimes \mathcal{A} \otimes \mathcal{B})$ and sets of local measurements for Alice and Bob.

► The winning probability for a monogamy-of-entanglement game using a standard quantum strategy is:

$$\sum_{x \in \Sigma} \pi(x) \sum_{a \in \Gamma} \left\langle R(a|x) \otimes A_a^x \otimes B_a^x, \rho \right\rangle.$$

The standard quantum value of a monogamy-of-entanglement game, G, denoted as $\omega^*(G)$, is the maximal winning probability for Alice and Bob over all standard quantum strategies.

Unentangled strategies for monogamy-of-entanglement games

In an $unentangled\ strategy$, the state ρ prepared by Alice and Bob is fully separable, that is

$$\{\rho_j^{\mathsf{R}}: j \in \Delta\} \subseteq \mathrm{D}(\mathcal{R}), \quad \{\rho_j^{\mathsf{A}}: j \in \Delta\} \subseteq \mathrm{D}(\mathcal{A}), \quad \{\rho_j^{\mathsf{B}}: j \in \Delta\} \subseteq \mathrm{D}(\mathcal{B}),$$

such that

$$\rho = \sum_{j \in \Delta} p(j) \rho_j^{\mathsf{R}} \otimes \rho_j^{\mathsf{A}} \otimes \rho_j^{\mathsf{B}}.$$

Unentangled strategies for monogamy-of-entanglement games

In an *unentangled strategy*, the state ρ prepared by Alice and Bob is fully separable, that is

$$\{\rho_j^{\mathsf{R}}: j \in \Delta\} \subseteq \mathrm{D}(\mathcal{R}), \quad \{\rho_j^{\mathsf{A}}: j \in \Delta\} \subseteq \mathrm{D}(\mathcal{A}), \quad \{\rho_j^{\mathsf{B}}: j \in \Delta\} \subseteq \mathrm{D}(\mathcal{B}),$$

such that

$$\rho = \sum_{j \in \Delta} p(j) \rho_j^{\mathsf{R}} \otimes \rho_j^{\mathsf{A}} \otimes \rho_j^{\mathsf{B}}.$$

Winning probability for an unentangled strategy is given by:

$$\sum_{x \in \Sigma} \pi(x) \sum_{a \in \Gamma} \left\langle R(a|x) \otimes A_a^{\times} \otimes B_a^{\times}, \rho \right\rangle$$

where ρ is separable.

The unentangled value, denoted as $\omega(G)$, is the supremum of the winning probability over all unentangled strategies.

13/29

Unentangled value for monogamy-of-entanglement games

- ▶ For $\omega(G)$, we want the *best* Alice and Bob can do.
- ▶ Since ρ is separable (no quantum correlations) we can imagine Alice and Bob optimizing functions $f: \Sigma \to \Gamma$ locally.

Unentangled value for monogamy-of-entanglement games

- ▶ For $\omega(G)$, we want the *best* Alice and Bob can do.
- ▶ Since ρ is separable (no quantum correlations) we can imagine Alice and Bob optimizing functions $f: \Sigma \to \Gamma$ locally.

Alice and Bob only win when their outputs agree, and we assume that the measurements of the referee are positive semidefinite (from the definition for monogamy-of-entanglement games).

► For any monogamy-of-entanglement game, *G*, the unentangled value is:

$$\omega(G) = \max_{f:\Sigma \to \Gamma} \left\| \sum_{x \in \Sigma} \pi(x) R(f(x)|x) \right\|,$$

where the maximum is over all functions $f: \Sigma \to \Gamma$.

The BB84 monogamy-of-entanglement game

The BB84 game $(G_{BB84} \text{ for short})^{\P}$ is defined by:

1. Question and answer sets:

$$\Sigma = \Gamma = \{0, 1\},\$$

2. Uniform probability for questions:

$$\pi(0) = \pi(1) = \frac{1}{2}$$

3. Measurements defined by the BB84 bases:

For
$$x = 0$$
: $R(0|0) = |0\rangle\langle 0|$, $R(1|0) = |1\rangle\langle 1|$
For $x = 1$: $R(0|1) = |+\rangle\langle +|$, $R(1|1) = |-\rangle\langle -|$

The unentangled and standard quantum values for G_{RB84} coincide:

$$\omega(G_{\text{BR84}}) = \omega^*(G_{\text{BR84}}) = \cos^2(\pi/8) \approx 0.8536$$

Demo Time: BB84 game BB84_GAME.M

A natural question for monogamy-of-entanglement games

▶ Question: For any monogamy-of-entanglement game, G, is it true that the *unentangled* and *standard quantum* values always coincide? In other words is it true that:

$$\omega(G) = \omega^*(G)$$

for all monogamy-of-entanglement games G?

Demo Time: Random monogamy-of-entanglement games RANDOM_MOE_GAMES.M

A natural question for monogamy-of-entanglement games

► Question: For any monogamy-of-entanglement game, G, is it true that the *unentangled* and *standard quantum* values always coincide? In other words is it true that:

$$\omega(G)=\omega^*(G)$$

for all monogamy-of-entanglement games *G*?

- Answer:
 - For certain cases: Yes.
 - ► In general: No.

$$\omega(G) = \omega^*(G)$$

In general No

Monogamy-of-entanglement games where $\omega(\textit{G}) \neq \omega^*(\textit{G})$

There exists a monogamy-of-entanglement game, G, with $|\Sigma|=4$ and $|\Gamma|=3$ such that

$$\omega(G) < \omega^*(G)$$
.

1. Question and answer sets:

$$\Sigma = \{0, 1, 2, 3\}, \quad \Gamma = \{0, 1, 2\}.$$

2. Uniform probability for questions:

$$\pi(0) = \pi(1) = \pi(2) = \pi(3) = \frac{1}{4}$$

3. Measurements defined by a mutually unbiased basis ¶:

$$\{R(0|x), R(1|x), R(2|x)\}.$$

Demo Time: Mutually unbiased basis game ${\rm MUB_4_3_GAME.M}$

Monogamy-of-entanglement games where $\omega(G) \neq \omega^*(G)$

An exhaustive search over all unentangled strategies reveals an optimal unentangled value:

$$\omega(G)=\frac{3+\sqrt{5}}{8}\approx 0.6545.$$

▶ Alternatively, a computer search over standard quantum strategies and a heuristic approximation for the upper bound of $\omega^*(G)$ reveals that:

$$2/3 \ge \omega^*(G) \ge 0.6609.$$

This ability to compute upper bounds for extended nonlocal games is obtained from an adaptation of a technique known as the *NPA hierarchy*.

$$\omega(G) = \omega^*(G)$$

For certain classes, Yes.

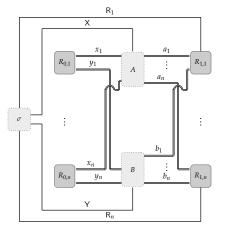

Monogamy games that obey $\omega(G) = \omega^*(G)$

Theorem (Johnston, Mittal, R, Watrous) For any monogamy-of-entanglement game, G, for which $|\Sigma|=2$: $\omega(G)=\omega^*(G)$.

Parallel repetition of monogamy-of-entanglement games

Parallel repetition of monogamy-of-entanglement games

- ▶ Parallel repetition: Run a monogamy-of-entanglement game, G, for n times in parallel, denoted as G^n .
- Strong parallel repetition: $\omega(G^n) = \omega(G)^n$

Question: Do all monogamy-of-entanglement games obey strong parallel repetition?

Parallel repetition of monogamy-of-entanglement games

► Recall:

$$\omega(G_{\text{BB84}}) = \omega^*(G_{\text{BB84}}) = \cos^2(\pi/8) \approx 0.8536.$$

• G_{BB84} obeys strong parallel repetition ¶:

$$\omega^*(G_{\mathsf{BB84}}^n) = \omega^*(G_{\mathsf{BB84}})^n = (\cos^2(\pi/8))^n$$
.

Demo Time: Strong parallel repetition of BB84 BB84_PARALLEL_REP.M

Upper bounds on strong parallel repetition for monogamy games

Theorem (Tomamichel, Fehr, Kaniewski, Wehner)

Let $G = (\pi, R)$ be a monogamy game where π is uniform over Σ . It holds that

$$\omega^*(G^n) \leq \left(\frac{1}{|\Sigma|} + \frac{|\Sigma| - 1}{|\Sigma|} \sqrt{c(G)}\right)^n$$

where c(G) is the "maximal overlap of measurements" of the referee

$$c(G) = \max_{\substack{x,y \in \Sigma \\ x \neq y}} \max_{a,b \in \Gamma} \left\| \sqrt{R(a|x)} \sqrt{R(b|y)} \right\|^2.$$

Strong parallel repetition for certain monogamy games

Theorem (Johnston, Mittal, R, Watrous)

Let $G=(\pi,R)$ be a monogamy game where $|\Sigma|=2$, π is uniform over Σ , and R(a|x) are projective operators. It holds that

$$\omega^*(G^n) = \left(\frac{1}{2} + \frac{1}{2}\sqrt{c(G)}\right)^n.$$

A key proposition and lemma

Lemma

Let Π_0 and Π_1 be nonzero projection operators on \mathbb{C}^n . It holds that

$$\|\Pi_0 + \Pi_1\| = 1 + \|\Pi_0\Pi_1\|.$$

Proposition

Let $G=(\pi,R)$ be a monogamy-of-entanglement game for which $\Sigma=\{0,1\}$, π is uniform over Σ , and R(a|x) is a projection operator for each $x\in\Sigma$ and $a\in\Gamma$. It holds that

$$\omega(G) = \frac{1}{2} + \frac{1}{2} \max_{a,b \in \Gamma} \left\| R(a|0)R(b|1) \right\|.$$

Proof of proposition

Recall that the unentangled value for any monogamy game G is written as

$$\omega(G) = \max_{f:\Sigma \to \Gamma} \left\| \sum_{x \in \Sigma} \pi(x) R(f(x)|x) \right\|.$$

Assuming the lemma stating $\|\Pi_0 + \Pi_1\| = 1 + \|\Pi_0\Pi_1\|$, we have

$$\omega(G) = \max_{a,b \in \Gamma} \left\| \frac{R(a|0) + R(b|1)}{2} \right\| = \frac{1}{2} + \frac{1}{2} \max_{a,b \in \Gamma} \left\| R(a|0)R(b|1) \right\|.$$

From the proposition that

$$\omega(G) = \frac{1}{2} + \frac{1}{2}\sqrt{c(G)}.$$

From the proposition that

$$\omega(G) = \frac{1}{2} + \frac{1}{2}\sqrt{c(G)}.$$

Since this is an unentangled strategy, we can assume that Alice and Bob just play every instance optimally (since there is no quantum correlation). It follows then that

$$\omega(G^n) = \left(\frac{1}{2} + \frac{1}{2}\sqrt{c(G)}\right)^n.$$

From the proposition that

$$\omega(G) = \frac{1}{2} + \frac{1}{2}\sqrt{c(G)}.$$

Since this is an unentangled strategy, we can assume that Alice and Bob just play every instance optimally (since there is no quantum correlation). It follows then that

$$\omega(G^n) = \left(\frac{1}{2} + \frac{1}{2}\sqrt{c(G)}\right)^n.$$

Recall that the theorem from [Tomamichel, Fehr, Kaniewski, Wehner, (2013)] gives us

$$\omega^*(G^n) \leq \left(\frac{1}{2} + \frac{1}{2}\sqrt{c(G)}\right)^n$$

which gives us that $\omega^*(G^n) \leq \omega(G^n)$.

From the proposition that

$$\omega(G) = \frac{1}{2} + \frac{1}{2}\sqrt{c(G)}.$$

Since this is an unentangled strategy, we can assume that Alice and Bob just play every instance optimally (since there is no quantum correlation). It follows then that

$$\omega(G^n) = \left(\frac{1}{2} + \frac{1}{2}\sqrt{c(G)}\right)^n.$$

Recall that the theorem from [Tomamichel, Fehr, Kaniewski, Wehner, (2013)] gives us

$$\omega^*(G^n) \leq \left(\frac{1}{2} + \frac{1}{2}\sqrt{c(G)}\right)^n$$

which gives us that $\omega^*(G^n) \leq \omega(G^n)$. Finally,

$$\omega^*(G^n) \ge \omega(G^n) \ge \left(\frac{1}{2} + \frac{1}{2} \max_{a,b \in \Gamma} \left\| R(a|0)R(b|1) \right\| \right)^n = \left(\frac{1}{2} + \frac{1}{2}\sqrt{c(G)}\right)^n.$$

Open questions

Unentangled vs. standard quantum strategies for monogamy-of-entanglement games

Inputs (Σ)	Outputs (Γ)	$\omega^*(G) = \omega(G)$	$\omega^*(G^n) = \omega^*(G)^n$	$\omega_{ns}(G^n) = \omega_{ns}(G)^n$
2	$ \Gamma \geq 1$	yes	yes	no
3	$ \Gamma \geq 1$?	?	no
4	3	no	?	no

Question: What about $|\Sigma| = 3$?

- ▶ Proof technique fails for $|\Sigma| > 2$.
- Computational search:
 - ▶ Generate random monogamy-of-entanglement games where $|\Sigma|=3$ and $|\Gamma|\geq 2$.
 - ▶ 10⁸ random games generates, no counterexamples found.

[¶]So long as the measurements used by the referee are projective and the probability distribution, π , from which the questions are asked is uniform.
